Ashutosh Kumar

Problem 1

A poker hand means a set of five cards selected at random from usual deck of playing cards.

1. Find the probability that it is a **Royal Flush** - means that it consists of ten, jack, queen, king, ace of one suit.
2. Find the probability that it is **Four of a kind** - means that there are four cards of equal face value.
3. Find the probability that it is a **Full house** - means that it consists of one pair and one triple of cards with equal face values.
4. Find the probability that it is a **Straight** - means that it consists of five cards in a sequence regardless of suit.
5. Find the probability that it consists of three cards of equal face value and two other cards but not a full house.
6. Find the probability that it consists of two distinct pairs and another card but does not fall into previous categories
7. Find the probability that it consists of a pair and three other cards but does not fall into previous categories

Solution

- 1.
- 2.
- 3.
- 4.
- 5.
- 6.
- 7.

Problem 2

In how many ways can eight rooks be placed on a chess board so that none can take another and none is on the white diagonal

Problem 3

A number X is chosen at random from the set $\{0, 1, 2, \dots, 10^n - 1\}$. Find the probability that X is a k -digit number. A number a is a k -digit number if it is of the form $a = \sum_0^{k-1} a_i 10^i$ where a_i are integers from 0 to 9 and a_{k-1} is not zero

Problem 4

One mapping is selected at random from the set of all mappings of $\{1, 2, \dots, n\}$.

1. What is the probability that the selected mapping transforms each of the n elements into 1?
2. What is the probability that element i has exactly k pre-images (Here i and k are pre-assigned) ?
3. What is the probability that the element i is transformed into j ?
4. What is the probability that the elements i_1, i_2 and i_3 (assume distinct) are transformed into j_1, j_2 and j_3 respectively?

Problem 5

One permutation is selected at random from the set of all permutations of $\{1, 2, \dots, n\}$.

1. What is the probability that the identity permutation is chosen?
2. What is the probability that the selected permutation transforms i_1, i_2, \dots, i_k into j_1, j_2, \dots, j_k respectively?
3. What is the probability that the permutation keeps i fixed?
4. What is the probability that the elements 1, 2 and 3 form a cycle in that order? (in some order?)
5. What is the probability that all the elements form a cycle?

Problem 6

1. Prove that in **Polya urn model**, chance of red ball is $r/(r+g)$ at any stage.
2. Show that red at stage m and green at stage $n \neq m$ equals $rg/\{(r+g)(r+g+1)\}$.
3. Do you think this will be the case in **Friedmans' model** where you add a ball of opposite colour?

Problem 7

A **tournament** is said to have k -leader property if for every set of k players there is one who beats them all. Consider a random tournament with n players. Fix k players. (Tournament on n vertices is a directed graph, having exactly one arrow between each pair of vertices.)

1. Show that the event "**No player beats all these k** ", has probability $(1 - 2^{-k})^{n-k}$
2. Consequently, if $\binom{n}{k}(1 - 2^{-k})^{n-k} < 1$, then there is a k -leader tournament with n players.
3. Show that for all large n this inequality holds and hence k -leader tournaments are possible
4. If $f(k)$ is the least such n , show that $f(1) = 3$ and $f(2) = 7$.

Problem 8

Three dice are rolled. Given that no two show the same face, find the conditional probability that at least one is an ace

Solution

$$P(A|B) = \frac{P(A \cap B)}{P(A)} \quad (1)$$

Let us first calculate the probability that of the three dice no two show the same face. Call that probability $P(A)$

For the first die, no of possibilities = 6

For the second die, no of possibilities = 5

For the third die, no of possibilities = 4

We know that total number of outcomes of the a three dice system are 6^3

Hence, we have

$$P(A) = \frac{6 \cdot 5 \cdot 4}{6^3}$$

We now calculate the probability that one of them is an ace.

There are three exclusive cases for this:

- a) Ace belongs to the first die,
- b) Ace belongs to the second die,
- c) Ace belongs to the third die.

Let us solve the a) case. The rest have similar arguments.

Given that ace is fixed in the first place, we have

For the second die, no of possibilities = 5

For the third die, no of possibilities = 4

A similar argument holds for the other cases.

Hence, we have

$$P(A \cap B) = \frac{3 \cdot 1 \cdot 5 \cdot 4}{6^3}$$

Using (1), we have:

$$\begin{aligned} P(A|B) &= \frac{3 \cdot 1 \cdot \cancel{5} \cdot \cancel{4}}{6 \cdot \cancel{5} \cdot \cancel{4}} \\ \implies P(A|B) &= \frac{1}{2} \end{aligned}$$

Problem 9

In a bolt factory; machines A , B and C manufacture 25, 35 and 40 percent of the total. Of their outputs 5, 4 and 2 percent are defective. A bolt selected at random is found to be defective. Given this what is the probability that it was manufactured by machine A ? by B ? by C ?

Problem 10

A die has four red faces and two white faces and a second die has two red and four white faces. A fair coin is flipped once. If it falls heads, we keep on throwing the first die and if it falls tails, we keep on throwing the second die.

1. Show that the probability of red at any throw is $\frac{1}{2}$
2. If the first two throws result in red what is the conditional probability of red at the third throw?
3. If red turns up at the first n throws, what is the conditional probability that the first die is being used?

Problem 11

An urn contains 3 white, 5 black and 2 red balls. Two persons draw balls in turn, without replacement. The first person to draw a white ball before the appearance of a red ball wins the game. However, if a red ball is drawn by anyone before the appearance of a white ball, then the game is declared a tie. Calculate the probability that:

1. The person who begins the game wins.
2. The other person wins.
3. The game ends in a tie.

Problem 12

I have two boxes. Box I has 4 red and 2 green balls while box II has 2 red and 4 green balls. I pick a ball at random from box I and put in box II; Then I pick a ball at random from box II and put in box I. Now I pick one ball from each box. What are the chances that they are of the same colour?

Problem 13

I throw a fair die. If 4, 5 or 6 show up, I put X as that value. If 1, 2 or 3 show up, I roll the die again and then put X as the sum of the two face obtained. Calculate the distribution of X .

Problem 14

For any events A_1, \dots, A_n in an experiment show $P(\bigcup A_i) \leq \sum P(A_i)$. This is called union bound (or Boole's inequality)

For any two events A and B show that

$$P(A \cap B) \geq P(A) + P(B) - 1$$

This is called a Bonferroni inequality.

The inclusion-exclusion formula we proved for probability of union of events is sometimes called Poincare formula.

Problem 15

Fix $0 < p < 1$. Then $G(n, p)$ is the (undirected) random graph model where we have n vertices and where edges are chosen independently each with probability p . Let q_n be the probability that the graph is disconnected. Show

$$q_n \leq \frac{1}{2} \sum_{k=1}^{n-1} \binom{n}{k} (1-p)^{k(n-k)} \leq \sum_{k=1}^{\lfloor n/2 \rfloor} (n(1-p)^{n/2})^k \rightarrow 0$$

Thus $1 - q_n \rightarrow 1$. This is expressed by saying that, in this model, almost every graph is connected. A better way to think is that, as n becomes large, our random graph is connected with overwhelming probability.

Problem 16

In an experiment $P(A) = 0.4$ and $P(A \cup B) = 0.7$. Determine $P(A)$ and $P(B)$ if:

1. A, B are independent.
2. A, B are disjoint.

Solution

1. Since A, B are independent, we know that $P(A \cap B) = P(A)P(B)$.
Also, we know that $P(A \cup B) = P(A) + P(B) - P(A \cap B)$

$$\begin{aligned}\text{On substituting, we get } 0.7 &= 0.4 + P(B) - 0.4 \times P(B) \\ \implies 0.3 &= P(B) - 0.4 \times P(B) \\ \implies 0.3 &= 0.6 \times P(B) \\ \implies P(B) &= 0.5\end{aligned}$$

2. Since A, B are disjoint, we know that $P(A \cap B) = 0$
 $0.7 = 0.4 + P(B)$
 $\implies P(B) = 0.3$

Problem 17

A cancer diagnostic test is 95% accurate both on those who have cancer and those who do not. Assume that 0.005 of some population have cancer. A person is selected at random and test shows he has cancer. Given this, what are the chances that he actually has cancer.

Problem 18

Banach carries (alright, assume he is alive!) two match boxes, each with 50 sticks, one in each pocket. When he needs, he selects one pocket and takes one match from that box.

1. Today for the first time he found that the box he picked is empty. What are the chances that the other box contains exactly k matches?
2. Today for the first time he is emptying a box. What are the chances that the other box contains exactly k matches?

Problem 19

In Chandrasekhar model, starting with zero balls (on day zero), the probability of having k balls on day one, two, three are respectively

$$e^{-\lambda} \lambda^k / k!; \quad e^{\lambda(1+q)} [\lambda(1+q)]^k / k!; \quad e^{\lambda(1+q+q^2)} [\lambda(1+q+q^2)]^k / k!$$

We did the first two. Do the third. Test your understanding by proving for day n using induction.

Problem 20

I roll a die twice. Find the distribution of:

1. The sum of the two scores obtained
2. Score 1 minus score 2
3. Maximum of the two scores
4. Minimum of the two scores

Problem 21

I toss a fair coin four times. Find the distribution of:
Number of head minus number of tails

Problem 22

I roll a fair die 100 times. Let X be the number of times face 3 appears. Find the distribution of X . What if the die was biased: chance of face i is p_i . Find the distribution of Y = number of times even face appears.

Problem 23

I have a fair die and a biased die for which chance of face i is proportional to i . I take a coin whose chance of heads is 0.3. I toss it. If heads up, I roll fair die. If tails up, I roll the biased die. Find the distribution of the face.

Problem 24

Suppose A_1, A_2, \dots, A_8 are independent events. Show that:

$$A_1 \cup A_2, \quad A_3 \cap A_4, \quad A_5^c \cup A_6^c, \quad A_7^c \cap A_8^c$$

are independent.

Problem 25

I have a coin whose chance of heads is p . I toss it n times (unless stated otherwise, tosses are independent). What is the most probable number of heads?

Problem 26

Two dice (unless stated otherwise, dice are fair) are thrown eight times. Find the probability of getting a score of 8 exactly four times. Here score in a throw is the sum of the faces on the two dice.

Problem 27

Game of **craps** is played as follows.

The player throws two dice. If score is 7 or 11, then he wins. If it is 2,3, or 12 then he loses. If it is anything else, he *continues throwing until he either throws the same score again or a seven. In the first case he wins and in the second case he loses. Calculate the probability of winning*

Problem 28

In a society there are equal number of males and females. A proportion α ($0 < \alpha < 1$) of males are colour blind and a proportion α^2 of females are colour blind. A person is chosen at random and found to be colour blind. Given this what are the chances that the person is a male?

Problem 29

A magician has a fair coin and a two-headed coin. He selects a coin and tosses it once. He gets H . Given this what are the chances that the coin is fair? He tosses a second time and gets T . Given this what are the chances that the coin is fair?

Problem 30

I give a letter to my friend to mail to you. The chances he forgets to mail are 0.1. Given that he mailed, the chances that it is not delivered by the post office to CMI are 0.1. Given that it is delivered to CMI, the chances you are not handed the letter are 0.1.

You did not receive the letter. Given this what are the chances that my friend forgot to mail? What are the chances my friend mailed but the post office did not deliver to CMI? What are the chances CMI got it but was not given to you?

Problem 31

I select two members at random, one after the other, from the set $\{1, 2, 3, 4, 5\}$ independently and make a rectangle with those as sides. Find the distribution of the area of the rectangle. Do both cases:

1. With replacement
2. Without replacement

Problem 32

Let $G = (V, E)$ be a graph (given to you). Choose points of V at random, each with probability $1/2$. Let T be the random set so obtained. Call an edge 'crossing edge' if one end is in T and the other in $V - T$. Since T is random, the number X of crossing edges is a random variable. Show that $E(X) = e/2$ where e is the number of edges, that is, cardinality of E .

Deduce that a graph with n vertices and e edges must have a bipartite subgraph with at least $e/2$ edges.

Here a subgraph of (V, E) means (V^*, E^*) where $V^* \subset V$; $E^* \subset E$. A graph (V, E) is bipartite if $V = V_1 \cup V_2$ with

1. $V_1 \neq \emptyset$ and $V_2 \neq \emptyset$;
2. $V_1 \cap V_2 = \emptyset$ and
3. Every edge has one vertex in V_1 and other in V_2

Problem 33

Consider a Erdos-Renyi random graph, where each edge is chosen, independent of others, with probability p . Say that a pair of vertices (unordered) is good, if either they are joined OR they are joined to a common vertex. Let X be the number of bad (not good) pairs. Since the graph is random, X is a random variable. Show that

$$E(X) \leq \binom{n}{2}(1 - p^2)^{n-2} \rightarrow 0$$

Deduce that $P(X \geq 1) \rightarrow 0$. Conclude that almost every graph has diameter 2.

Diameter of a graph is the largest possible distance between pairs of vertices and distance between a pair of vertices is the number of edges in the shortest path joining them (if no such path exists between a pair of vertices then the distance between them is ∞).

Problem 34

The four students in Msc(App), each toss a fair coin twice. Student i obtains X_i , number of heads. I make a 2×2 matrix with rows (X_1, X_2) and (X_3, X_4) . What are the chances that this matrix is non-singular? What are the chances that this matrix is symmetric?

Problem 35

Consider the set $S = \{0, 1, 2, \dots, 11\}$ with addition and multiplication modulo 12. I pick a number at random from S . What are the chances that it has a multiplicative inverse?

Problem 36

To pick a subset of $X = \{1, 2, 3, 4, 5\}$ at random I must write down all the 32 subsets of X and pick one of them at random.

Someone told me that I can toss a fair coin *for each* $i(1 \leq i \leq 5)$ and pick i when heads comes up and do not pick i when tails come up. The set so obtained is a random subset.

Do you agree?
